# Total Bond Energies of Exact Classical Solutions of Molecules Generated by Millsian 1.0 Compared to Those Computed Using Modern 3-21G and 6-31G* Basis Sets 

R. L. Mills, B. Holverstott, B. Good, N. Hogle, A. Makwana<br>Millsian, Inc., 493 Old Trenton Road, Cranbury, NJ 08512, www.millsian.com

#### Abstract

Mills [1-12] solved the structure of the bound electron using classical laws and subsequently developed a unification theory based on those laws called the Grand Unified Theory of Classical Physics (GUTCP) with results that match observations for the basic phenomena of physics and chemistry from the scale of the quarks to cosmos. Millsian 1.0 is a program comprising molecular modeling applications of GUTCP, solving atomic and molecular structures based on applying the classical laws of physics, (Newton's and Maxwell's Laws) to the atomic scale. The functional groups of all major classes of chemical bonding including those involved in most organic molecules have been solved exactly in closed-form solutions. By using these functional groups as building blocks, or independent units, a potentially infinite number of molecules can be solved. As a result, Millsian software can visualize the exact three-dimensional structure and calculate physical characteristics of almost any molecule of any length and complexity. Even complex proteins and DNA (the molecules that encode genetic information) can be solved in real-time interactively on a personal computer. By contrast, previous software based on traditional quantum methods must resort to approximations and run on powerful computers for even the simplest systems. The energies of exact classical solutions of molecules generated by Millsian 1.0 and those from a modern quantum mechanics-based program, Spartan's precomputed database using 3-21G and $6-31 \mathrm{G}^{*}$ basis sets at the Hartree-Fock level of theory, were compared to experimental values. The Millsian results were consistently within an average relative deviation of about $0.1 \%$ of the experimentally values. In contrast, the $3-21 \mathrm{G}$ and $6-31 \mathrm{G}^{*}$ results deviated over a wide range of relative error, typically being $>30-150 \%$ with a large percentage of catastrophic failures, depending on functional group type and basis set.

## I. INTRODUCTION

In this paper, the old view that the electron is a zero or one-dimensional point in an allspace probability wave function $\Psi(x)$ is not taken for granted. Rather, atomic and molecular physics theory, derived from first principles, must successfully and consistently apply physical laws on all scales [1-12]. Stability to radiation was ignored by all past atomic models, but in this case, it is the basis of the solutions wherein the structure of the electron is first solved and the result determines the nature of the atomic and molecular electrons involved in chemical bonds.

Historically, the point at which quantum mechanics broke with classical laws can be traced to the issue of nonradiation of the one electron atom. Bohr just postulated orbits stable to radiation with the further postulate that the bound electron of the hydrogen atom does not obey Maxwell's equations-rather it obeys different physics [1-12]. Later physics was replaced by "pure mathematics" based on the notion of the inexplicable wave-particle duality nature of electrons which lead to the Schrödinger equation wherein the consequences of radiation predicted by Maxwell's equations were ignored. Ironically, Bohr, Schrödinger, and Dirac used the Coulomb potential, and Dirac used the vector potential of Maxwell's equations. But, all ignored electrodynamics and the corresponding radiative consequences. Dirac originally attempted to solve the bound electron physically with stability with respect to radiation according to Maxwell's equations with the further constraints that it was relativistically invariant and gave rise to electron spin [13]. He and many founders of QM such as Sommerfeld, Bohm, and Weinstein wrongly pursued a planetary model, were unsuccessful, and resorted to the current mathematical-probability-wave model that has many problems [1-17]. Consequently, Feynman for example, attempted to use first principles including Maxwell's equations to discover new physics to replace quantum mechanics [18].

Starting with the same essential physics as Bohr, Schrödinger, and Dirac of $e^{-}$moving in the Coulombic field of the proton and an electromagnetic wave equation and matching electron source current rather than an energy diffusion equation originally sought by Schrödinger, advancements in the understanding of the stability of the bound electron to radiation are applied to solve for the exact nature of the electron. Rather than using the postulated Schrödinger boundary condition: " $\Psi \rightarrow 0$ as $r \rightarrow \infty$ ", which leads to a purely mathematical model of the electron, the constraint is based on experimental observation. Using Maxwell's equations, the structure of the electron is derived as a boundary-value problem wherein the electron comprises the source current of time-varying electromagnetic fields during transitions with the constraint that the bound $n=1$ state electron cannot radiate energy. Although it is well known that an accelerated point particle radiates, an extended distribution modeled as a superposition of accelerating charges does not have to radiate. The physical boundary condition of nonradiation
of that was imposed on the bound electron follows from a derivation by Haus [19]. The function that describes the motion of the electron must not possess spacetime Fourier components that are synchronous with waves traveling at the speed of light. Similarly, nonradiation is demonstrated based on the electron's electromagnetic fields and the Poynting power vector. A simple invariant physical model arises naturally wherein the results are extremely straightforward, internally consistent, and predictive of conjugate parameters for the first time, requiring minimal math as in the case of the most famous exact equations (no uncertainty) of Newton and Maxwell on which the model is based. No new physics is needed; only the known physical laws based on direct observation are used.

The structure of the bound atomic electron was solved by first considering one-electron atoms [1-12]. Since the hydrogen atom is stable and nonradiative, the electron has constant energy. Furthermore, it is time dynamic with a corresponding current that serves as a source of electromagnetic radiation during transitions. The wave equation solutions of the radiation fields permit the source currents to be determined as a boundary-value problem. These source currents match the field solutions of the wave equation for two dimensions plus time and the nonradiative $n=1$ state when the nonradiation condition is applied. Then, the mechanics of the electron can be solved from the two-dimensional wave equation plus time in the form of an energy equation wherein it provides for conservation of energy and angular momentum as given in the Electron Mechanics and the Corresponding Classical Wave Equation for the Derivation of the Rotational Parameters of the Electron section of Ref. [1]. Once the nature of the electron is solved, all problems involving electrons can be solved in principle. Thus, in the case of one-electron atoms, the electron radius, binding energy, and other parameters are solved after solving for the nature of the bound electron.

For time-varying spherical electromagnetic fields, Jackson [20] gives a generalized expansion in vector spherical waves that are convenient for electromagnetic boundary-value problems possessing spherical symmetry properties and for analyzing multipole radiation from a localized source distribution. The Green function $G\left(\mathbf{x}^{\prime}, \mathbf{x}\right)$ which is appropriate to the equation

$$
\begin{equation*}
\left(\nabla^{2}+k^{2}\right) G\left(\mathbf{x}^{\prime}, \mathbf{x}\right)=-\delta\left(\mathbf{x}^{\prime}-\mathbf{x}\right) \tag{1}
\end{equation*}
$$

in the infinite domain with the spherical wave expansion for the outgoing wave Green function is

$$
\begin{equation*}
G\left(\mathbf{x}^{\prime}, \mathbf{x}\right)=\frac{e^{-i k\left|\mathbf{x}-\mathbf{x}^{\prime}\right|}}{4 \pi\left|\mathbf{x}-\mathbf{x}^{\prime}\right|}=i k \sum_{\ell=0}^{\infty} j_{\ell}\left(k r_{<}\right) h_{\ell}^{(1)}\left(k r_{>}\right) \sum_{m=-\ell}^{\ell} Y_{\ell, m}^{*}\left(\theta^{\prime}, \phi^{\prime}\right) Y_{\ell, m}(\theta, \phi) \tag{2}
\end{equation*}
$$

Jackson [20] further gives the general multipole field solution to Maxwell's equations in a source-free region of empty space with the assumption of a time dependence $e^{i \omega_{n} t}$ :

$$
\begin{align*}
& \mathbf{B}=\sum_{\ell, m}\left[a_{E}(\ell, m) f_{\ell}(k r) \mathbf{X}_{\ell . m}-\frac{i}{k} a_{M}(\ell, m) \nabla \times g_{\ell}(k r) \mathbf{X}_{\ell . m}\right] \\
& \mathbf{E}=\sum_{\ell, m}\left[\frac{i}{k} a_{E}(\ell, m) \nabla \times f_{\ell}(k r) \mathbf{X}_{\ell . m}+a_{M}(\ell, m) g_{\ell}(k r) \mathbf{X}_{\ell . m}\right] \tag{3}
\end{align*}
$$

where the cgs units used by Jackson are retained in this section. The radial functions $f_{\ell}(k r)$ and $g_{\ell}(k r)$ are of the form:

$$
\begin{equation*}
g_{\ell}(k r)=A_{\ell}^{(1)} h_{\ell}^{(1)}+A_{\ell}^{(2)} h_{\ell}^{(2)} \tag{4}
\end{equation*}
$$

$\mathbf{X}_{\ell . m}$ is the vector spherical harmonic defined by

$$
\begin{equation*}
\mathbf{X}_{\ell, m}(\theta, \phi)=\frac{1}{\sqrt{\ell(\ell+1)}} \mathbf{L} Y_{\ell, m}(\theta, \phi) \tag{5}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathbf{L}=\frac{1}{i}(\mathbf{r} \times \nabla) \tag{6}
\end{equation*}
$$

The coefficients $a_{E}(\ell, m)$ and $a_{M}(\ell, m)$ of Eq. (3) specify the amounts of electric ( $\ell, m$ ) multipole and magnetic $(\ell, m)$ multipole fields, and are determined by sources and boundary conditions as are the relative proportions in Eq. (4). Jackson gives the result of the electric and magnetic coefficients from the sources as

$$
\begin{equation*}
a_{E}(\ell, m)=\frac{4 \pi k^{2}}{i \sqrt{\ell(\ell+1)}} \int Y_{\ell}^{m^{*}}\left\{\rho \frac{\partial}{\partial r}\left[r j_{\ell}(k r)\right]+\frac{i k}{c}(\mathbf{r} \cdot \mathbf{J}) j_{\ell}(k r)-i k \nabla \cdot(r \times \boldsymbol{M}) j_{\ell}(k r)\right\} d^{3} x \tag{7}
\end{equation*}
$$

and

$$
\begin{equation*}
a_{M}(\ell, m)=\frac{-4 \pi k^{2}}{\sqrt{\ell(\ell+1)}} \int j_{\ell}(k r) Y_{\ell}^{m^{*}} \mathbf{L} \cdot\left(\frac{\mathbf{J}}{c}+\nabla \times \boldsymbol{M}\right) d^{3} x \tag{8}
\end{equation*}
$$

respectively, where the distribution of charge $\rho(\mathbf{x}, t)$, current $\mathbf{J}(\mathbf{x}, t)$, and intrinsic magnetization $\boldsymbol{M}(\mathbf{x}, t)$ are harmonically varying sources: $\rho(\mathbf{x}) e^{-i \omega t}, \mathbf{J}(\mathbf{x}) e^{-i \omega t}$, and $\boldsymbol{M}(\mathbf{x}) e^{-i \omega t}$.

The electron current-density function can be solved as a boundary value problem regarding the time varying corresponding source current $\mathbf{J}(\mathbf{x}) e^{-i \omega t}$ that gives rise to the timevarying spherical electromagnetic fields during transitions between states with the further constraint that the electron is nonradiative in a state defined as the $n=1$ state. The potential energy, $V(\mathbf{r})$, is an inverse-radius-squared relationship given by given by Gauss' law which for a point charge or a two-dimensional spherical shell at a distance $r$ from the nucleus the potential is

$$
\begin{equation*}
V(r)=-\frac{e^{2}}{4 \pi \varepsilon_{0} r} \tag{9}
\end{equation*}
$$

Thus, consideration of conservation of energy would require that the electron radius must be fixed. Addition constraints requiring a two-dimensional source current of fixed radius are matching the delta function of Eq. (1) with no singularity, no time dependence and consequently no radiation, absence of self-interaction (See Appendix IV of Ref. [1]), and exact electroneutrality of the hydrogen atom wherein the electric field is given by

$$
\begin{equation*}
\mathbf{n} \bullet\left(\mathbf{E}_{1}-\mathbf{E}_{2}\right)=\frac{\sigma_{s}}{\varepsilon_{0}} \tag{10}
\end{equation*}
$$

where $\mathbf{n}$ is the normal unit vector, $\mathbf{E}_{1}$ and $\mathbf{E}_{2}$ are the electric field vectors that are discontinuous at the opposite surfaces, $\sigma_{s}$ is the discontinuous two-dimensional surface charge density, and $\mathbf{E}_{2}=0$. Then, the solution for the radial electron function, which satisfies the boundary conditions is a delta function in spherical coordinates-a spherical shell [21]

$$
\begin{equation*}
f(r)=\frac{1}{r^{2}} \delta\left(r-r_{n}\right) \tag{11}
\end{equation*}
$$

where $r_{n}$ is an allowed radius. This function defines the charge density on a spherical shell of a fixed radius (See Figure 1), not yet determined, with the charge motion confined to the twodimensional spherical surface. The integer subscript $n$ is determined during photon absorption as given in the Excited States of the One-Electron Atom (Quantization) section of Ref. [1]. It is shown in this section that the force balance between the electric fields of the electron and proton plus any resonantly absorbed photons gives the result that $r_{n}=n r_{1}$ wherein $n$ is an integer in an excited state.

Given time harmonic motion and a radial delta function, the relationship between an allowed radius and the electron wavelength is given by

$$
\begin{equation*}
2 \pi r_{n}=\lambda_{n} \tag{12}
\end{equation*}
$$

Based on conservation of the electron's angular momentum of $\hbar$, the magnitude of the velocity and the angular frequency for every point on the surface of the bound electron are

$$
\begin{align*}
& v_{n}=\frac{h}{m_{e} \lambda_{n}}=\frac{h}{m_{e} 2 \pi r_{n}}=\frac{\hbar}{m_{e} r_{n}}  \tag{13}\\
& \omega_{n}=\frac{\hbar}{m_{e} r_{n}^{2}} \tag{14}
\end{align*}
$$

To further match the required multipole electromagnetic fields between transitions of states, the trial nonradiative source current functions are time and spherical harmonics, each having an exact radius and an exact energy. Then, each allowed electron charge-density (mass-density) function is the product of a radial delta function $\left(f(r)=\frac{1}{r^{2}} \delta\left(r-r_{n}\right)\right)$, two angular functions (spherical harmonic functions $\left.Y_{\ell}^{m}(\theta, \phi)=P_{\ell}^{m}(\cos \theta) e^{i m \phi}\right)$, and a time-harmonic function $e^{i m \omega_{n} t}$. The spherical harmonic $Y_{0}^{0}(\theta, \phi)=1$ is also an allowed solution that is in fact required in order
for the electron charge and mass densities to be positive definite and to give rise to the phenomena of electron spin. The real parts of the spherical harmonics vary between -1 and 1 . But the mass of the electron cannot be negative; and the charge cannot be positive. Thus, to insure that the function is positive definite, the form of the angular solution must be a superposition:

$$
\begin{equation*}
Y_{0}^{0}(\theta, \phi)+Y_{\ell}^{m}(\theta, \phi) \tag{15}
\end{equation*}
$$

The current is constant at every point on the surface for the s orbital corresponding to $Y_{0}^{0}(\theta, \phi)$. The quantum numbers of the spherical harmonic currents can be related to the observed electron orbital angular momentum states. The currents corresponding to $s, p, d, f$, etc. orbitals are $\ell=0$

$$
\begin{equation*}
\rho(r, \theta, \phi, t)=\frac{e}{8 \pi r^{2}}\left[\delta\left(r-r_{n}\right)\right]\left[Y_{0}^{0}(\theta, \phi)+Y_{\ell}^{m}(\theta, \phi)\right] \tag{16}
\end{equation*}
$$

$\ell \neq 0$

$$
\begin{equation*}
\rho(r, \theta, \phi, t)=\frac{e}{4 \pi r^{2}}\left[\delta\left(r-r_{n}\right)\right]\left[Y_{0}^{0}(\theta, \phi)+\operatorname{Re}\left\{Y_{\ell}^{m}(\theta, \phi) e^{i m \omega_{n} t}\right\}\right] \tag{17}
\end{equation*}
$$

where $Y_{\ell}^{m}(\theta, \phi)$ are the spherical harmonic functions that spin about the z-axis with angular frequency $\omega_{n}$ with $Y_{0}^{0}(\theta, \phi)$ the constant function and $\operatorname{Re}\left\{Y_{\ell}^{m}(\theta, \phi) e^{i m \omega_{n} t}\right\}=P_{\ell}^{m}(\cos \theta) \cos \left(m \phi+m \omega_{n} t\right)$.

The Fourier transform of the electron charge-density function is a solution of the fourdimensional wave equation in frequency space ( $\mathbf{k}, \omega$-space). Then the corresponding Fourier transform of the current-density function $K(s, \Theta, \Phi, \omega)$ is given by multiplying by the constant angular frequency corresponding to a potentially emitted photon.

$$
\begin{align*}
& K(s, \Theta, \Phi, \omega)=4 \pi \omega_{n} \frac{\sin \left(2 s_{n} r_{n}\right)}{2 s_{n} r_{n}} \otimes 2 \pi \sum_{v=1}^{\infty} \frac{(-1)^{v-1}(\pi \sin \Theta)^{2(v-1)}}{(v-1)!(v-1)!} \frac{\Gamma\left(\frac{1}{2}\right) \Gamma\left(v+\frac{1}{2}\right)}{(\pi \cos \Theta)^{2 v+1} 2^{v+1}} \frac{2 v!}{(v-1)!} s^{-2 v} \\
& \otimes 2 \pi \sum_{v=1}^{\infty} \frac{(-1)^{v-1}(\pi \sin \Phi)^{2(v-1)}}{(v-1)!(v-1)!} \frac{\Gamma\left(\frac{1}{2}\right) \Gamma\left(v+\frac{1}{2}\right)}{(\pi \cos \Phi)^{2 v+1} 2^{v+1}} \frac{2 v!}{(v-1)!} s^{-2 v} \frac{1}{4 \pi}\left[\delta\left(\omega-\omega_{n}\right)+\delta\left(\omega+\omega_{n}\right)\right] \tag{18}
\end{align*}
$$

The motion on the orbitsphere is angular; however, a radial correction exists due to special relativistic effects. When the velocity is $c$ corresponding to a potentially emitted photon

$$
\begin{equation*}
\mathbf{s}_{n} \bullet \mathbf{v}_{n}=\mathbf{s}_{n} \bullet \mathbf{c}=\omega_{n} \tag{19}
\end{equation*}
$$

the relativistically corrected wavelength is (Eq. (1.247) of Ref. [1])

$$
\begin{equation*}
r_{n}=\lambda_{n} \tag{20}
\end{equation*}
$$

Substitution of Eq. (20) into the sinc function results in the vanishing of the entire Fourier
transform of the current-density function. Thus, spacetime harmonics of $\frac{\omega_{n}}{c}=k$ or $\frac{\omega_{n}}{c} \sqrt{\frac{\varepsilon}{\varepsilon_{o}}}=k$ for which the Fourier transform of the current-density function is nonzero do not exist. Radiation due to charge motion does not occur in any medium when this boundary condition is met. There is acceleration without radiation. (Also see Abbott and Griffiths and Goedecke [2223]). Nonradiation is also shown directly using Maxwell's equations directly in Appendix I of Ref. [1]. However, in the case that such a state arises as an excited state by photon absorption, it is radiative due to a radial dipole term in its current-density function since it possesses spacetime Fourier transform components synchronous with waves traveling at the speed of light as shown in the Instability of Excited States section of Ref. [1]. The radiation emitted or absorbed during electron transitions is the multipole radiation given by Eq. (2) as given in the Excited States of the One-Electron Atom (Quantization) section and the Equation of the Photon section of Ref. [1] wherein Eqs. (4.18-4.23) give a macro-spherical wave in the far-field.

In Chapter 1 of Ref. [1], the uniform current density function $Y_{0}^{0}(\theta, \phi)$ (Eqs. (16-17)) that gives rise to the spin of the electron is generated from two current-vector fields (CVFs). Each CVF comprises a continuum of correlated orthogonal great circle current-density elements (one dimensional "current loops"). The current pattern comprising each CVF is generated over a half-sphere surface by a set of rotations of two orthogonal great circle current loops that serve as basis elements about each of the $\left(-\mathbf{i}_{x}, \mathbf{i}_{y}, 0 \mathbf{i}_{z}\right)$ and $\left(-\frac{1}{\sqrt{2}} \mathbf{i}_{x}, \frac{1}{\sqrt{2}} \mathbf{i}_{y}, \mathbf{i}_{z}\right)$-axis; the span being $\pi$ radians. Then, the two CVFs are convoluted, and the result is normalized to exactly generate the continuous uniform electron current density function $Y_{0}^{0}(\theta, \phi)$ covering a spherical shell and having the three angular momentum components of $\mathbf{L}_{x y}=+/-\frac{\hbar}{4}(+/-$ designates both the positive and negative vector directions along an axis in the xy-plane) and $\mathbf{L}_{z}=\frac{\hbar}{2}$. The z-axis view of a representation of the total current pattern of the $Y_{0}^{0}(\theta, \phi)$ orbitsphere comprising the superposition of 144 current elements is shown in Figure 2A. As the number of great circles goes to infinity the current distribution becomes continuous and is exactly uniform following normalization. A representation of the $\left(-\frac{1}{\sqrt{2}} \mathbf{i}_{x}, \frac{1}{\sqrt{2}} \mathbf{i}_{y}, \mathbf{i}_{z}\right)$-axis view of the total uniform current-density pattern of the $Y_{0}{ }^{0}(\phi, \theta)$ orbitsphere with 144 vectors overlaid on the continuous bound-electron current density giving the direction of the current of each great circle element is shown in Figure 2B. This superconducting current pattern is confined to two spatial dimensions.

Thus, a bound electron is a constant two-dimensional spherical surface of charge (zero thickness and total charge $=-e$ ), called an electron orbitsphere that can exist in a bound state at only specified distances from the nucleus determined by an energy minimum for the $n=1$ state and integer multiples of this radius due to the action of resonant photons as shown in the

Determination of Orbitsphere Radii section and Excited States of the One-Electron Atom (Quantization) section of Ref. [1], respectively. The bound electron is not a point, but it is pointlike (behaves like a point at the origin). The free electron is continuous with the bound electron as it is ionized and is also point-like as shown in the Electron in Free Space section of Ref. [1]. The total function that describes the spinning motion of each electron orbitsphere is composed of two functions. One function, the spin function (see Figure 1 for the charge function and Figure 2 for the current function), is spatially uniform over the orbitsphere, where each point moves on the surface with the same quantized angular and linear velocity, and gives rise to spin angular momentum. It corresponds to the nonradiative $n=1, \ell=0$ state of atomic hydrogen which is well known as an s state or orbital. The other function, the modulation function, can be spatially uniform - in which case there is no orbital angular momentum and the magnetic moment of the electron orbitsphere is one Bohr magneton-or not spatially uniform-in which case there is orbital angular momentum. The modulation function rotates with a quantized angular velocity about a specific (by convention) z-axis. The constant spin function that is modulated by a time and spherical harmonic function as given by Eq. (17) is shown in Figure 3 for several $\ell$ values. The modulation or traveling charge-density wave that corresponds to an orbital angular momentum in addition to a spin angular momentum are typically referred to as $\mathrm{p}, \mathrm{d}$, f , etc. orbitals and correspond to an $\ell$ quantum number not equal to zero.

It was shown previously [1-12] that classical physics gives closed form solutions for the atom including the stability of the $n=1$ state and the instability of the excited states, the equation of the photon and electron in excited states, the equation of the free electron, and photon which predict the wave particle duality behavior of particles and light. The current and charge density functions of the electron may be directly physically interpreted. For example, spin angular momentum results from the motion of negatively charged mass moving systematically, and the equation for angular momentum, $\mathbf{r} \times \mathbf{p}$, can be applied directly to the wavefunction (a current density function) that describes the electron. The magnetic moment of a Bohr magneton, Stern Gerlach experiment, g factor, Lamb shift, resonant line width and shape, selection rules, correspondence principle, wave-particle duality, excited states, reduced mass, rotational energies, and momenta, orbital and spin splitting, spin-orbital coupling, Knight shift, and spin-nuclear coupling, and elastic electron scattering from helium atoms, are derived in closed form equations based on Maxwell's equations. The agreement between observations and predictions based on closed-form equations with fundamental constants only matches to the limit permitted by the error in the measured fundamental constants.

In contrast to the failure of the Bohr theory and the nonphysical, unpredictive, adjustableparameter approach of quantum mechanics, multielectron atoms [1, 4] and the nature of the chemical bond $[1,5]$ are given by exact closed-form solutions containing fundamental constants
only. Using the nonradiative electron current-density functions, the radii are determined from the force balance of the electric, magnetic, and centrifugal forces that correspond to the minimum of energy of the atomic or ionic system. The ionization energies are then given by the electric and magnetic energies at these radii. The spreadsheets to calculate the energies from exact solutions of one through twenty-electron atoms are available from the internet [24]. For 400 atoms and ions the agreement between the predicted and experimental results are remarkable [4]. In this paper, we extend these results to the nature of the chemical bond. In this regard, quantum mechanics has historically sought the lowest energy of the molecular system, but this is trivially the case of the electrons inside the nuclei. Obviously, the electrons must obey additional physical laws since matter does not exist in a state with the electrons collapsed into the nuclei. Specifically, molecular bonding is due to the physics of Newton's and Maxwell's laws together with achieving an energy minimum.

The structure of the bound molecular electron was solved by first considering the oneelectron molecule $H_{2}^{+}$and then the simplest molecule $H_{2}[1,5]$. The nature of the chemical bond was solved in the same fashion as that of the bound atomic electron. First principles including stability to radiation requires that the electron charge of the molecular orbital is a prolate spheroid, a solution of the Laplacian as an equipotential minimum energy surface in the natural ellipsoidal coordinates compared to spheroidal in the atomic case, and the current is time harmonic and obeys Newton's laws of mechanics in the central field of the nuclei at the foci of the spheroid. There is no a priori reason why the electron position must be a solution of the three-dimensional wave equation plus time and cannot comprise source currents of electromagnetic waves that are solutions of the three-dimensional wave equation plus time. Then, the special case of nonradiation determines that the current functions are confined to twospatial dimensions plus time and match the electromagnetic wave-equation solutions for these dimensions. In addition to the important result of stability to radiation, several more very important physical results are subsequently realized: (i) The charge is distributed on a twodimension surface; thus, there are no infinities in the corresponding fields (Eq. (10)). Infinite fields are simply renormalized in the case of the point-particles of quantum mechanics, but it is physically gratifying that none arise in this case since infinite fields have never been measured or realized in the laboratory. (ii) The hydrogen molecular ion or molecule has finite dimensions rather than extending over all space. From measurements of the resistivity of hydrogen as a function of pressure, the finite dimensions of the hydrogen molecule are evident in the plateau of the resistivity versus pressure curve of metallic hydrogen [25]. This is in contradiction to the predictions of quantum probability functions such as an exponential radial distribution in space. Furthermore, despite the predictions of quantum mechanics that preclude the imaging of a
molecule orbital, the full three-dimensional structure of the outer molecular orbital of $N_{2}$ has been recently tomographically reconstructed [26]. The charge-density surface observed is similar to that shown in Figure 4 for $H_{2}$ which is direct evidence that MO's electrons are not point-particle probability waves that have no form until they are "collapsed to a point" by measurement. Rather they are physical, two-dimensional equipotential charge density functions as derived herein. (iii) Consistent with experiments, neutral scattering is predicted without violation of special relativity and causality wherein a point must be everywhere at once as required in the QM case. (iv) There is no electron self-interaction. The continuous chargedensity function is a two-dimensional equipotential energy surface with an electric field that is strictly normal for the elliptic parameter $\xi>0$ according to Gauss' law and Faraday's law. The relationship between the electric field equation and the electron source charge-density function is given by Maxwell's equation in two dimensions [27,28] (Eq. (10)). This relation shows that only a two-dimensional geometry meets the criterion for a fundamental particle. This is the nonsingularity geometry that is no longer divisible. It is the dimension from which it is not possible to lower dimensionality. In this case, there is no electrostatic self-interaction since the corresponding potential is continuous across the surface according to Faraday's law in the electrostatic limit, and the field is discontinuous, normal to the charge according to Gauss' law [27-29]. (v) The instability of electron-electron repulsion of molecular hydrogen is eliminated since the central field of the hydrogen molecular ion relative to a second electron at $\xi>0$ which binds to form the hydrogen molecule is that of a single charge at the foci. (vi) The ellipsoidal MOs allow exact spin pairing over all time that is consistent with experimental observation. This aspect is not possible in the QM model.

Current algorithms to solve molecules are based on nonphysical models based on the concept that the electron is a zero or one-dimensional point in an all-space probability wave function $\Psi(x)$ that permits the electron to be over all space simultaneously and give output based on trial and error or direct empirical adjustment of parameters. These models ultimately cannot be the actual description of a physical electron in that they inherently violate physical laws. They suffer from the same shortcomings that plague atomic quantum theory, infinities, instability with respect to radiation according to Maxwell's equations, violation of conservation of linear and angular momentum, lack of physical relativistic invariance, and the electron is unbounded such that the edge of molecues does not exist. There is no uniqueness, as exemplified by the average of 150 internally inconsistent programs per molecule for each of the 788 molecules posted on the NIST website [30]. Furthermore, from a physical perspective, the implication for the basis of the chemical bond according to quantum mechanics being the exchange integral and the requirement of zero-point vibration, "strictly quantum mechanical
phenomena," is that the theory cannot be a correct description of reality as described for even the simple bond of molecular hydrogen as reported previous [1,5]. Even the premise that "electron overlap" is responsible for bonding is opposite to the physical reality that negative charges repel each other with an inverse-distance-squared force dependence that becomes infinite. A proposed solution based on physical laws and fully compliant with Maxwell's equations solves the parameters of molecules even to infinite length and complexity in closed form equations with fundamental constants only.

For the first time in history, the key building blocks of organic chemistry have been solved from two basic equations. Now, the true physical structure and parameters of an infinite number of organic molecules up to infinite length and complexity can be obtained to permit the engineering of new pharmaceuticals and materials at the molecular level. The solutions of the basic functional groups of organic chemistry were obtained by using generalized forms of a geometrical and an energy equation for the nature of the $H-H$ bond. The geometrical parameters and total bond energies of about 800 exemplary organic molecules were calculated using the functional group composition. The results obtained essentially instantaneously match the experimental values typically to the limit of measurement [1]. The solved function groups are given in Table 1.

The two basic equations that solves organic molecules, one for geometrical parameters and the other for energy parameters, were applied to bulk forms of matter containing trillions of trillions of electrons. For example, using the same alkane- and alkene-bond solutions as elements in an infinite network, the nature of the solid molecular bond for all known allotropes of carbon (graphite, diamond, $C_{60}$, and their combinations) were solved. By further extension of this modular approach, the solid molecular bond of silicon and the nature of semiconductor bond were solved. The nature of other fundamental forms of matter such as the nature of the ionic bond, the metallic bond, and additional major fields of chemistry such as that of silicon, organometallics, and boron were solved exactly such that the position and energy of each and every electron is precisely specified. The implication of these results is that it is possible using physical laws to solve the structure of all types of matter. Some of the solved forms of matter of infinite extent as well as additional major fields of chemistry are given in Table 2. In all cases, the agreement with experiment is remarkable [1].

## II. METHODOLOGICAL OUTLINE

## A. The Nature of the Chemical Bond of Hydrogen

The nature of the chemical bond of functional groups is solved by first solving the simplest molecule, molecular hydrogen as given in the Nature of the Chemical Bond of Hydrogen-Type Molecules section of Ref. [1]. The hydrogen molecule charge and current
density functions, bond distance, and energies are solved from the Laplacian in ellipsoidal coordinates with the constraint of nonradiation $[1,5]$.

$$
\begin{equation*}
(\eta-\zeta) R_{\xi} \frac{\partial}{\partial \xi}\left(R_{\xi} \frac{\partial \phi}{\partial \xi}\right)+(\zeta-\xi) R_{\eta} \frac{\partial}{\partial \eta}\left(R_{\eta} \frac{\partial \phi}{\partial \eta}\right)+(\xi-\eta) R_{\zeta} \frac{\partial}{\partial \zeta}\left(R_{\zeta} \frac{\partial \phi}{\partial \zeta}\right)=0 \tag{21}
\end{equation*}
$$

## a. The Geometrical Parameters of the Hydrogen Molecule

As shown in Figure 4, the nuclei are at the foci of the electrons comprising a twodimensional, equipotential-energy, charge- and current-density surface that obeys Maxwell's equations including stability to radiation and Newton's laws of motion. The force balance equation for the hydrogen molecule is

$$
\begin{equation*}
\frac{\hbar^{2}}{m_{e} a^{2} b^{2}} D=\frac{e^{2}}{8 \pi \varepsilon_{o} a b^{2}} D+\frac{\hbar^{2}}{2 m_{e} a^{2} b^{2}} D \tag{22}
\end{equation*}
$$

where

$$
\begin{equation*}
D=\mathbf{r}(t) \cdot \mathbf{i}_{\xi} \tag{23}
\end{equation*}
$$

is the time dependent distance from the origin to the tangent plane at a point on the ellipsoidal MO. Eq. (22) has the parametric solution

$$
\begin{equation*}
r(t)=\mathbf{i} a \cos \omega t+\mathbf{j} b \sin \omega t \tag{24}
\end{equation*}
$$

when the semimajor axis, $a$, is

$$
\begin{equation*}
a=a_{o} \tag{25}
\end{equation*}
$$

The internuclear distance, $2 c^{\prime}$, which is the distance between the foci is

$$
\begin{equation*}
2 c^{\prime}=\sqrt{2} a_{o} \tag{26}
\end{equation*}
$$

The experimental internuclear distance is $\sqrt{2} a_{o}$. The semiminor axis is

$$
\begin{equation*}
b=\frac{1}{\sqrt{2}} a_{o} \tag{27}
\end{equation*}
$$

The eccentricity, $e$, is

$$
\begin{equation*}
e=\frac{1}{\sqrt{2}} \tag{28}
\end{equation*}
$$

## b. The Energies of the Hydrogen Molecule

The potential energy of the two electrons in the central field of the protons at the foci is

$$
\begin{equation*}
V_{e}=\frac{-2 e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-67.836 \mathrm{eV} \tag{29}
\end{equation*}
$$

The potential energy of the two protons is

$$
\begin{equation*}
V_{p}=\frac{e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}}=19.242 \mathrm{eV} \tag{30}
\end{equation*}
$$

The kinetic energy of the electrons is

$$
\begin{equation*}
T=\frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=33.918 \mathrm{eV} \tag{31}
\end{equation*}
$$

The energy, $V_{m}$, of the magnetic force between the electrons is

$$
\begin{equation*}
V_{m}=\frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}=-16.959 \mathrm{eV} \tag{32}
\end{equation*}
$$

During bond formation, the electrons undergo a reentrant oscillatory orbit with vibration of the protons. The corresponding energy $\bar{E}_{\text {osc }}$ is the difference between the Doppler and average vibrational kinetic energies:

$$
\begin{equation*}
\bar{E}_{o s c}=\bar{E}_{D}+\bar{E}_{K v i b}=\left(V_{e}+T+V_{m}+V_{p}\right) \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}} \tag{33}
\end{equation*}
$$

The total energy is

$$
\begin{gather*}
E_{T}=V_{e}+T+V_{m}+V_{p}+\bar{E}_{\text {osc }}  \tag{34}\\
E_{T}=-\frac{e^{2}}{8 \pi \varepsilon_{o} a_{0}}\left[\left(2 \sqrt{2}-\sqrt{2}+\frac{\sqrt{2}}{2}\right) \ln \frac{\sqrt{2}+1}{\sqrt{2}-1}-\sqrt{2}\right]\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{e^{2}}{m_{e} a_{0}^{3}}}}{m_{e} c^{2}}}\right]-\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}=-31.689 \mathrm{eV} \tag{35}
\end{gather*}
$$

The energy of two hydrogen atoms is

$$
\begin{equation*}
E\left(2 H\left[a_{H}\right]\right)=-27.21 \mathrm{eV} \tag{36}
\end{equation*}
$$

The bond dissociation energy, $E_{D}$, is the difference between the total energy of the corresponding hydrogen atoms (Eq. (36)) and $E_{T}$ (Eq. (35)).

$$
\begin{equation*}
E_{D}=E\left(2 H\left[a_{H}\right]\right)-E_{T}=4.478 \mathrm{eV} \tag{37}
\end{equation*}
$$

The experimental energy is $E_{D}=4.478 \mathrm{eV}$. The calculated and experimental parameters of $H_{2}$, $D_{2}, H_{2}^{+}$, and $D_{2}^{+}$from Ref. [5] and Chp. 11 of Ref. [1] are given in Table 3.

## B. Derivation of the General Geometrical and Energy Equations of Organic Chemistry

Organic molecules comprising an arbitrary number of atoms can be solved using similar principles and procedures as those used to solve alkanes of arbitrary length. Alkanes can be considered to be comprised of the functional groups of $\mathrm{CH}_{3}, \mathrm{CH}_{2}$, and $\mathrm{C}-\mathrm{C}$. These groups with the corresponding geometrical parameters and energies can be added as a linear sum to give the solution of any straight chain alkane as shown in the Continuous-Chain Alkanes section of Ref. [1]. Similarly, the geometrical parameters and energies of all functional groups such as those given in Table 1 can be solved. The functional-group solutions can be made into a linear superposition and sum, respectively, to give the solution of any organic molecule. The solutions of the functional groups can be conveniently obtained by using generalized forms of the geometrical and energy equations. The derivation of the dimensional parameters and energies of the function groups are given in the Nature of the Chemical Bond of Hydrogen-Type Molecules, Polyatomic Molecular Ions and Molecules, More Polyatomic Molecules and Hydrocarbons, and Organic Molecular Functional Groups and Molecules sections of Ref. [1]. (Reference to equations of the form Eq. (15.number), Eq. (11.number), Eq. (13.number), and Eq. (14.number) will refer to the corresponding equations of Ref. [1].) Additional derivations for other nonorganic function groups given in Table 2 are derived in the following sections of Ref. [1]: Applications: Pharmaceuticals, Specialty Molecular Functional Groups and Molecules, Dipole Moments, and Interactions, Nature of the Solid Molecular Bond of the Three Allotropes of Carbon, Silicon Molecular Functional Groups and Molecules, Nature of the Solid Semiconductor Bond of Silicon, Boron Molecues, and Organometallic Molecular Functional Groups and Molecules sections.

Consider the case wherein at least two atomic orbital hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum, and the sharing of electrons between two or more such orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. The force-generalized constant $k^{\prime}$ of a $H_{2}$-type ellipsoidal MO due to the equivalent of two point charges of at the foci is given by:

$$
\begin{equation*}
k^{\prime}=\frac{C_{1} C_{2} 2 e^{2}}{4 \pi \varepsilon_{0}} \tag{38}
\end{equation*}
$$

where $C_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of a chemical bond of the molecule or molecular ion which is 0.75 (Eq. (13.59)) in the case of $H$ bonding to a central atom and 0.5 (Eq. (14.152)) otherwise, and $C_{2}$ is the factor that results in an equipotential energy match of the participating at least two molecular or atomic orbitals of the chemical bond. From Eqs. (13.58-13.63), the distance from the origin of the MO to each focus $c^{\prime}$ is given by:

$$
\begin{equation*}
c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 C_{1} C_{2} a}}=\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{39}
\end{equation*}
$$

The internuclear distance is

$$
\begin{equation*}
2 c^{\prime}=2 \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}} \tag{40}
\end{equation*}
$$

The length of the semiminor axis of the prolate spheroidal MO $b=c$ is given by

$$
\begin{equation*}
b=\sqrt{a^{2}-c^{\prime 2}} \tag{41}
\end{equation*}
$$

And, the eccentricity, $e$, is

$$
\begin{equation*}
e=\frac{c^{\prime}}{a} \tag{42}
\end{equation*}
$$

From Eqs. (11.207-11.212), the potential energy of the two electrons in the central field of the nuclei at the foci is

$$
\begin{equation*}
V_{e}=n_{1} c_{1} c_{2} \frac{-2 e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{43}
\end{equation*}
$$

The potential energy of the two nuclei is

$$
\begin{equation*}
V_{p}=n_{1} \frac{e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}} \tag{44}
\end{equation*}
$$

The kinetic energy of the electrons is

$$
\begin{equation*}
T=n_{1} c_{1} c_{2} \frac{\hbar^{2}}{2 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{45}
\end{equation*}
$$

And, the energy, $V_{m}$, of the magnetic force between the electrons is

$$
\begin{equation*}
V_{m}=n_{1} c_{1} c_{2} \frac{-\hbar^{2}}{4 m_{e} a \sqrt{a^{2}-b^{2}}} \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}} \tag{46}
\end{equation*}
$$

The total energy of the $H_{2}$-type prolate spheroidal MO, $E_{T}\left(H_{2} M O\right)$, is given by the sum of the energy terms:

$$
\begin{align*}
E_{T}\left(H_{2} M O\right) & =V_{e}+T+V_{m}+V_{p}  \tag{47}\\
E_{T}\left(H_{2} M O\right) & =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]  \tag{48}\\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]
\end{align*}
$$

where $n_{1}$ is the number of equivalent bonds of the MO. $c_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of an MO which is 0.75 (Eqs. (13.67-13.73)) in the case of $H$ bonding to an unhybridized central atom and 1 otherwise, and $c_{2}$ is the factor that results in an equipotential energy match of the participating the MO and the at least two atomic orbitals of the
chemical bond. Specifically, to meet the equipotential condition and energy matching conditions for the union of the $\mathrm{H}_{2}$-type-ellipsoidal-MO and the HOs or AOs of the bonding atoms, the factor $c_{2}$ of a $H_{2}$-type ellipsoidal MO may given by (i) one, (ii) the ratio of the Coulombic or valence energy of the AO or HO of at least one atom of the bond and 13.605804 eV , the Coulombic energy between the electron and proton of $H$, (iii) the ratio of the valence energy of the AO or HO of one atom and the Coulombic energy of another, (iv) the ratio of the valence energies of the AOs or HOs of two atoms, (v) the ratio of two $c_{2}$ factors corresponding to any of cases (ii)-(iv), and (vi) the product of two different $c_{2}$ factors corresponding to any of the cases (i)-(v). Specific examples of the factor $c_{2}$ of a $H_{2}$-type ellipsoidal MO given in previously [1] are
0.936127 , the ratio of the ionization energy of $N 14.53414 \mathrm{eV}$ and 13.605804 eV , the Coulombic energy between the electron and proton of $H$;
0.91771 , the ratio of $14.82575 \mathrm{eV},-E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$, and 13.605804 eV ;
0.87495 , the ratio of $15.55033 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {ethane }}, 2 s p^{3}\right)$, and 13.605804 eV ;
0.85252 , the ratio of $15.95955 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {ethylene }}, 2 s p^{3}\right)$, and 13.605804 eV ;
0.85252 , the ratio of $15.95955 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {benzene }}, 2 s p^{3}\right)$, and 13.605804 eV , and
0.86359 , the ratio of $15.55033 \mathrm{eV},-E_{\text {Coulomb }}\left(C_{\text {alkane }}, 2 s p^{3}\right)$, and 13.605804 eV .

In the generalization of the hybridization of at least two atomic-orbital shells to form a shell of hybrid orbitals, the hybridized shell comprises a linear combination of the electrons of the atomic-orbital shells. The radius of the hybridized shell is calculated from the total Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and that the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons. The total energy $E_{T}\left(\right.$ atom, $\left.m s p^{3}\right)$ ( $m$ is the integer of the valence shell) of the AO electrons and the hybridized shell is given by the sum of energies of successive ions of the atom over the $n$ electrons comprising total electrons of the at least one AO shell.

$$
\begin{equation*}
E_{T}\left(\text { atom }, m s p^{3}\right)=-\sum_{m=1}^{n} I P_{m} \tag{49}
\end{equation*}
$$

where $I P_{m}$ is the $m$ th ionization energy (positive) of the atom. The radius $r_{m s s^{3}}$ of the hybridized shell is given by:

$$
\begin{equation*}
r_{m s p^{3}}=\sum_{q=Z-n}^{Z-1} \frac{-(Z-q) e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { atom }, m s p^{3}\right)} \tag{50}
\end{equation*}
$$

Then, the Coulombic energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by

$$
\begin{equation*}
E_{\text {Coulomb }}\left(\text { atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}} \tag{51}
\end{equation*}
$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) at the initial radius $r$ of the AO electron:

$$
\begin{equation*}
E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}}=\frac{8 \pi \mu_{o} \mu_{B}^{2}}{r^{3}} \tag{52}
\end{equation*}
$$

Then, the energy $E\left(\right.$ atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ and $E$ (magnetic):

$$
\begin{equation*}
E\left(\text { atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}} \tag{53}
\end{equation*}
$$

Consider next that the at least two atomic orbitals hybridize as a linear combination of electrons at the same energy in order to achieve a bond at an energy minimum with another atomic orbital or hybridized orbital. As a further generalization of the basis of the stability of the MO, the sharing of electrons between two or more such hybridized orbitals to form a MO permits the participating hybridized orbitals to decrease in energy through a decrease in the radius of one or more of the participating orbitals. In this case, the total energy of the hybridized orbitals is given by the sum of $E\left(\right.$ atom, $\left.m s p^{3}\right)$ and the next energies of successive ions of the atom over the $n$ electrons comprising the total electrons of the at least two initial AO shells. Here, $E\left(\right.$ atom, $\left.m s p^{3}\right)$ is the sum of the first ionization energy of the atom and the hybridization energy. An example of $E\left(\right.$ atom, $\left.m s p^{3}\right)$ for $E\left(C, 2 s p^{3}\right)$ is given in Eq. (14.503) where the sum of the negative of the first ionization energy of $C,-11.27671 \mathrm{eV}$, plus the hybridization energy to form the $C 2 s p^{3}$ shell given by Eq. (14.146) is $E\left(C, 2 s p^{3}\right)=-14.63489 \mathrm{eV}$.

Thus, the sharing of electrons between two atom msp ${ }^{3}$ HOs to form an atom-atom-bond MO permits each participating hybridized orbital to decrease in radius and energy. In order to further satisfy the potential, kinetic, and orbital energy relationships, each atom $\mathrm{msp}^{3} \mathrm{HO}$ donates an excess of $25 \%$ per bond of its electron density to the atom-atom-bond MO to form an energy minimum wherein the atom-atom bond comprises one of a single, double, or triple bond. In each case, the radius of the hybridized shell is calculated from the Coulombic energy equation by considering that the central field decreases by an integer for each successive electron of the shell and the total energy of the shell is equal to the total Coulombic energy of the initial AO electrons plus the hybridization energy. The total energy $E_{T}$ (mol.atom, $m s p^{3}$ ) ( $m$ is the integer of the valence shell) of the HO electrons is given by the sum of energies of successive ions of the atom over the $n$ electrons comprising total electrons of the at least one initial AO shell and the
hybridization energy:

$$
\begin{equation*}
E_{T}\left(\text { mol.atom }, m s p^{3}\right)=E\left(\text { atom }, m s p^{3}\right)-\sum_{m=2}^{n} I P_{m} \tag{54}
\end{equation*}
$$

where $I P_{m}$ is the $m$ th ionization energy (positive) of the atom and the sum of $-I P_{1}$ plus the hybridization energy is $E$ (atom, $\left.m s p^{3}\right)$. Thus, the radius $r_{m s p^{3}}$ of the hybridized shell due to its donation of a total charge $-Q e$ to the corresponding MO is given by is given by:

$$
\begin{align*}
r_{m s p^{3}} & =\left(\sum_{q=Z-n}^{Z-1}(Z-q)-Q\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { mol.atom, } \text { msp }^{3}\right)}  \tag{55}\\
& =\left(\sum_{q=Z-n}^{Z-1}(Z-q)-s(0.25)\right) \frac{-e^{2}}{8 \pi \varepsilon_{0} E_{T}\left(\text { mol.atom, } m s p^{3}\right)}
\end{align*}
$$

where $-e$ is the fundamental electron charge and $s=1,2,3$ for a single, double, and triple bond, respectively. The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$ of the outer electron of the atom $m s p^{3}$ shell is given by

$$
\begin{equation*}
E_{\text {Coulomb }}\left(\text { mol.atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}} \tag{56}
\end{equation*}
$$

In the case that during hybridization at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) at the initial radius $r$ of the AO electron given by Eq. (52). Then, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}$ (mol.atom, msp ${ }^{3}$ ) and $E$ (magnetic) :

$$
\begin{equation*}
E\left(\text { mol.atom }, m s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{m s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}} \tag{57}
\end{equation*}
$$

$E_{T}\left(\right.$ atom-atom,$\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of the atom-atom-bond MO is given by the difference between $E$ (mol.atom,msp ${ }^{3}$ ) and $E\left(\right.$ atom, $\left.m s p^{3}\right)$ :

$$
\begin{equation*}
E_{T}\left(\text { atom }- \text { atom }, m s p^{3}\right)=E\left(\text { mol.atom }, m s p^{3}\right)-E\left(\text { atom }, m s p^{3}\right) \tag{58}
\end{equation*}
$$

In the case of the $C 2 s p^{3} \mathrm{HO}$, the initial parameters (Eqs. (14.142-14.146)) are

$$
\begin{align*}
& r_{2 s p^{3}}=\sum_{n=2}^{5} \frac{(Z-n) e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=\frac{10 e^{2}}{8 \pi \varepsilon_{0}(e 148.25751 \mathrm{eV})}=0.91771 a_{0}  \tag{59}\\
& E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} 0.91771 a_{0}}=-14.82575 \mathrm{eV}  \tag{60}\\
& E(\text { magnetic })=\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}}=\frac{8 \pi \mu_{0} \mu_{B}^{2}}{\left(0.84317 a_{0}\right)^{3}}=0.19086 \mathrm{eV} \tag{61}
\end{align*}
$$

$$
\begin{align*}
E\left(C, 2 s p^{3}\right) & =\frac{-e^{2}}{8 \pi \varepsilon_{0} r_{2 s p^{3}}}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(r_{3}\right)^{3}} \\
& =-14.82575 \mathrm{eV}+0.19086 \mathrm{eV}  \tag{62}\\
& =-14.63489 \mathrm{eV}
\end{align*}
$$

In Eq. (55),

$$
\begin{equation*}
\sum_{q=Z-n}^{Z-1}(Z-q)=10 \tag{63}
\end{equation*}
$$

Eqs. (14.147) and (54) give

$$
\begin{equation*}
E_{T}\left(\text { mol.atom }, m s p^{3}\right)=E_{T}\left(C_{\text {ethane }}, 2 s p^{3}\right)=-151.61569 \mathrm{eV} \tag{64}
\end{equation*}
$$

Using Eqs. (55-65), the final values of $r_{C 2 s p^{3}}, E_{\text {Coulomb }}\left(C 2 s p^{3}\right)$, and $E\left(C 2 s p^{3}\right)$, and the resulting $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ of the MO due to charge donation from the HO to the MO where $C^{B O}-C$ refers to the bond order of the carbon-carbon bond for different values of the parameter $s$ are given in Table 4.

In another generalized case of the basis of forming a minimum-energy bond with the constraint that it must meet the energy matching condition for all MOs at all HOs or AOs, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell of each bonding atom must be the average of $E$ (mol.atom, $m s p^{3}$ ) for two different values of $s$ :

$$
\begin{equation*}
E\left(\text { mol.atom }, m s p^{3}\right)=\frac{E\left(\operatorname{mol} . \operatorname{atom}\left(s_{1}\right), m s p^{3}\right)+E\left(\operatorname{mol} . \operatorname{atom}\left(s_{2}\right), m s p^{3}\right)}{2} \tag{65}
\end{equation*}
$$

In this case, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO, is average for two different values of $s$ :

$$
\begin{equation*}
E_{T}\left(\operatorname{atom}-\operatorname{atom}, m s p^{3}\right)=\frac{E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{1}\right), m s p^{3}\right)+E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{2}\right), m s p^{3}\right)}{2} \tag{66}
\end{equation*}
$$

Consider an aromatic molecule such as benzene given in the Benzene Molecule section of Ref. [1]. Each $C=C$ double bond comprises a linear combination of a factor of 0.75 of four paired electrons (three electrons) from two sets of two $C 2 s p^{3}$ HOs of the participating carbon atoms. Each $C-H$ bond of $C H$ having two spin-paired electrons, one from an initially unpaired electron of the carbon atom and the other from the hydrogen atom, comprises the linear combination of $75 \% \mathrm{H}_{2}$-type ellipsoidal MO and $25 \% C 2 s p^{3} \mathrm{HO}$ as given by Eq. (13.439). However, $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$ of the $C-H$-bond MO is given by $0.5 E_{T}\left(C=C, 2 s p^{3}\right)$ (Eq. (14.247)) corresponding to one half of a double bond that matches the condition for a singlebond order for $\mathrm{C}-H$ that is lowered in energy due to the aromatic character of the bond.

A further general possibility is that a minimum-energy bond is achieved with satisfaction of the potential, kinetic, and orbital energy relationships by the formation of an MO comprising an allowed multiple of a linear combination of $\mathrm{H}_{2}$-type ellipsoidal MOs and corresponding HOs or AOs that contribute a corresponding allowed multiple (e.g. $0.5,0.75,1$ ) of the bond order given in Table 4. For example, the alkane MO given in the Continuous-Chain Alkanes section of Ref. [1] comprises a linear combination of factors of 0.5 of a single bond and 0.5 of a double bond.

Consider a first MO and its HOs comprising a linear combination of bond orders and a second MO that shares a HO with the first. In addition to the mutual HO , the second MO comprises another AO or HO having a single bond order or a mixed bond order. Then, in order for the two MOs to be energy matched, the bond order of the second MO and its HOs or its HO and AO is a linear combination of the terms corresponding to the bond order of the mutual HO and the bond order of the independent HO or AO. Then, in general, $E_{T}\left(\right.$ atom - atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO, is a weighted linear sum for different values of $s$ that matches the energy of the bonded MOs, HOs, and AOs:

$$
\begin{equation*}
E_{T}\left(\text { atom }- \text { atom }, m s p^{3}\right)=\sum_{n=1}^{N} c_{s_{n}} E_{T}\left(\operatorname{atom}-\operatorname{atom}\left(s_{n}\right), m s p^{3}\right) \tag{67}
\end{equation*}
$$

where $c_{s_{n}}$ is the multiple of the BO of $s_{n}$. The radius $r_{m s p^{3}}$ of the atom $m s p^{3}$ shell of each bonding atom is given by the Coulombic energy using the initial energy $E_{\text {Coulomb }}\left(\right.$ atom, $\left.m s p^{3}\right)$ and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of each atom-atom-bond MO:

$$
\begin{equation*}
r_{m s p^{3}}=\frac{-e^{2}}{8 \pi \varepsilon_{0} a_{0}\left(E_{\text {Coulonb }}\left(\text { atom }, m s p^{3}\right)+E_{T}\left(\text { atom }- \text { atom }, m s p^{3}\right)\right)} \tag{68}
\end{equation*}
$$

where $\quad E_{\text {Coulomb }}\left(C 2 s p^{3}\right)=-14.825751 \mathrm{eV}$. The Coulombic energy $E_{\text {Coulomb }}$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by Eq. (56). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) (Eq. (52)) at the initial radius $r$ of the AO electron. Then, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}\left(\right.$ mol.atom, msp ${ }^{3}$ ) and $E$ (magnetic) (Eq. (57)). $\quad E_{T}\left(\right.$ atom-atom,msp $\left.{ }^{3}\right)$, the energy change of each atom $m s p^{3}$ shell with the formation of the atom-atom-bond MO is given by the difference between $E$ (mol.atom, $m s p^{3}$ ) and $E$ (atom, $m s p^{3}$ ) given by Eq. (58). Using Eq. (60)
for $E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)$ in Eq. (68), the single bond order energies given by Eqs. (55-64) and shown in Table 4, and the linear combination energies (Eqs. (65-67)), the parameters of linear combinations of bond orders and linear combinations of mixed bond orders are given in Table 5.

Consider next the radius of the AO or HO due to the contribution of charge to more than one bond. The energy contribution due to the charge donation at each atom such as carbon superimposes linearly. In general, the radius $r_{\text {mol2sp }}$ of the $C 2 s p^{3} \mathrm{HO}$ of a carbon atom of a given molecule is calculated using Eq. (14.514) by considering $\sum E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)$, the total energy donation to all bonds with which it participates in bonding. The general equation for the radius is given by

$$
\begin{align*}
r_{\text {mol } 2 s p^{3}} & =\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+\sum E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right)} \\
& =\frac{e^{2}}{8 \pi \varepsilon_{0}\left(e 14.825751 \mathrm{eV}+\sum\left|E_{T_{\text {mol }}}\left(M O, 2 s p^{3}\right)\right|\right)} \tag{69}
\end{align*}
$$

The Coulombic energy $E_{\text {Coulomb }}\left(\right.$ mol.atom, $m s p^{3}$ ) of the outer electron of the atom msp ${ }^{3}$ shell is given by Eq. (56). In the case that during hybridization, at least one of the spin-paired AO electrons is unpaired in the hybridized orbital (HO), the energy change for the promotion to the unpaired state is the magnetic energy $E$ (magnetic) (Eq. (52)) at the initial radius $r$ of the AO electron. Then, the energy $E$ (mol.atom, $m s p^{3}$ ) of the outer electron of the atom $m s p^{3}$ shell is given by the sum of $E_{\text {Coulomb }}$ (mol.atom, msp ${ }^{3}$ ) and $E$ (magnetic) (Eq. (57)).

For example, the $C 2 s p^{3} \mathrm{HO}$ of each methyl group of an alkane contributes -0.92918 eV (Eq. (14.513)) to the corresponding single $C-C$ bond; thus, the corresponding $C 2 s p^{3} \mathrm{HO}$ radius is given by Eq. (14.514). The $C 2 s p^{3} \mathrm{HO}$ of each methylene group of $C_{n} H_{2 n+2}$ contributes -0.92918 eV to each of the two corresponding $C-C$ bond MOs. Thus, the radius (Eq. (69)), the Coulombic energy (Eq. (56)), and the energy (Eq. (57)) of each alkane methylene group are

$$
\begin{align*}
& r_{\text {alkane }_{\text {melthlyene }} \text { spp }}=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(E_{\text {Coulomb }}\left(C, 2 s p^{3}\right)+\sum E_{T_{\text {alkene }}}\left(\text { methylene } C-C, 2 s p^{3}\right)\right)} \\
& =\frac{e^{2}}{8 \pi \varepsilon_{0}(e 14.825751 \mathrm{eV}+e 0.92918 \mathrm{eV}+e 0.92918 \mathrm{eV})}  \tag{70}\\
& =0.81549 a_{0} \\
& E_{\text {Coulomb }}\left(C_{\text {methylene }} 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(0.81549 a_{0}\right)}=-16.68412 \mathrm{eV}  \tag{71}\\
& E\left(C_{\text {methylene }} 2 s p^{3}\right)=\frac{-e^{2}}{8 \pi \varepsilon_{0}\left(0.81549 a_{0}\right)}+\frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}\left(0.84317 a_{0}\right)^{3}}=-16.49325 \mathrm{eV} \tag{72}
\end{align*}
$$

In the determination of the parameters of functional groups, heteroatoms bonding to $C 2 s p^{3}$ HOs to form MOs are energy matched to the $C 2 s p^{3}$ HOs. Thus, the radius and the energy parameters of a bonding heteroatom are given by the same equations as those for $C 2 s p^{3}$ HOs. Using Eqs. (52), (56-57), (61), and (69) in a generalized fashion, the final values of the radius of the HO or $\mathrm{AO}, r_{\text {Atom.HO.AO }}, E_{\text {Coulomb }}\left(\right.$ mol.atom, $\left.m s p^{3}\right)$, and $E\left(C_{\text {mol }} 2 s p^{3}\right)$ are calculated using $\sum E_{T_{\text {group }}}\left(M O, 2 s p^{3}\right)$, the total energy donation to each bond with which an atom participates in bonding corresponding to the values of $E_{T}\left(C^{B O}-C, C 2 s p^{3}\right)$ of the MO due to charge donation from the AO or HO to the MO given in Tables 4 and 5.

The energy of the MO is matched to each of the participating outermost atomic or hybridized orbitals of the bonding atoms wherein the energy match includes the energy contribution due to the AO or HO's donation of charge to the MO. The force constant $k^{\prime}$ (Eq. (38)) is used to determine the ellipsoidal parameter $c^{\prime}$ (Eq. (39)) of the each $H_{2}$-type-ellipsoidal-MO in terms of the central force of the foci. Then, $c^{\prime}$ is substituted into the energy equation (from Eq. (48))) which is set equal to $n_{1}$ times the total energy of $H_{2}$ where $n_{1}$ is the number of equivalent bonds of the MO and the energy of $\mathrm{H}_{2},-31.63536831 \mathrm{eV}$, Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO. From the energy equation and the relationship between the axes, the dimensions of the MO are solved. The energy equation has the semimajor axis $a$ as it only parameter. The solution of the semimajor axis $a$ then allows for the solution of the other axes of each prolate spheroid and eccentricity of each MO (Eqs. (4042)). The parameter solutions then allow for the component and total energies of the MO to be determined.

The total energy, $E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)$, is given by the sum of the energy terms (Eqs. (43-48)) plus $E_{T}(A O / H O)$ :

$$
\begin{align*}
E_{T}\left(H_{2} M O\right) & =V_{e}+T+V_{m}+V_{p}+E_{T}(A O / H O)  \tag{73}\\
E_{T}\left(H_{2} M O\right) & =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{o} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]+E_{T}(A O / H O)  \tag{74}\\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}(A O / H O)
\end{align*}
$$

where $n_{1}$ is the number of equivalent bonds of the $\mathrm{MO}, c_{1}$ is the fraction of the $H_{2}$-type ellipsoidal MO basis function of a chemical bond of the group, $c_{2}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of each chemical bond, and $E_{T}(A O / H O)$ is the total energy comprising the difference of the energy $E(A O / H O)$ of at least one atomic or hybrid orbital to which the MO is energy matched and any
energy component $\Delta E_{\mathrm{H}_{2} M O}(A O / H O)$ due to the AO or HO's charge donation to the MO.

$$
\begin{equation*}
E_{T}(A O / H O)=E(A O / H O)-\Delta E_{H_{2} M O}(A O / H O) \tag{75}
\end{equation*}
$$

To solve the bond parameters and energies, $c^{\prime}=a \sqrt{\frac{\hbar^{2} 4 \pi \varepsilon_{0}}{m_{e} e^{2} 2 C_{1} C_{2} a}}=\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}$ (Eq. (39)) is substituted into $E_{T}\left(H_{2} M O\right)$ to give

$$
\begin{align*}
E_{T}\left(H_{2} M O\right) & =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{a^{2}-b^{2}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{a^{2}-b^{2}}}{a-\sqrt{a^{2}-b^{2}}}-1\right]+E_{T}(A O / H O) \\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} c^{\prime}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+c^{\prime}}{a-c^{\prime}}-1\right]+E_{T}(A O / H O)  \tag{76}\\
& =-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right]+E_{T}(A O / H O)
\end{align*}
$$

The total energy is set equal to $E$ (basis energies) which in the most general case is given by the sum of a first integer $n_{1}$ times the total energy of $H_{2}$ minus a second integer $n_{2}$ times the total energy of $H$, minus a third integer $n_{3}$ times the valence energy of $E(A O)$ (e.g. $E(N)=-14.53414 \mathrm{eV}$ ) where the first integer can be $1,2,3 \ldots$, and each of the second and third integers can be $0,1,2,3 \ldots$.

$$
\begin{equation*}
E(\text { basis energies })=n_{1}(-31.63536831 \mathrm{eV})-n_{2}(-13.605804 \mathrm{eV})-n_{3} E(A O) \tag{77}
\end{equation*}
$$

In the case that the MO bonds two atoms other than hydrogen, $E$ (basis energies) is $n_{1}$ times the total energy of $H_{2}$ where $n_{1}$ is the number of equivalent bonds of the MO and the energy of $H_{2}$, -31.63536831 eV , Eq. (11.212) is the minimum energy possible for a prolate spheroidal MO:
$E($ basis energies $)=n_{1}(-31.63536831 \mathrm{eV})$
$E_{T}\left(\mathrm{H}_{2} \mathrm{MO}\right)$, is set equal to $E$ (basis energies), and the semimajor axis $a$ is solved. Thus, the semimajor axis $a$ is solved from the equation of the form:

$$
\begin{equation*}
-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right]+E_{T}(A O / H O)=\text { E(basis energies) } \tag{79}
\end{equation*}
$$

The distance from the origin of the $H_{2}$-type-ellipsoidal-MO to each focus $c^{\prime}$, the internuclear distance $2 c^{\prime}$, and the length of the semiminor axis of the prolate spheroidal $H_{2}$-type MO $b=c$ are solved from the semimajor axis $a$ using Eqs. (39-41). Then, the component energies are given by Eqs. (43-46) and (76).

The total energy of the MO of the functional group, $E_{T}(м о)$, is the sum of the total energy
of the components comprising the energy contribution of the MO formed between the participating atoms and $E_{T}\left(\right.$ atom-atom, $\left.m s p^{3} . A O\right)$, the change in the energy of the AOs or HOs upon forming the bond. From Eqs. (76-77), $E_{T}(м о)$ is

$$
\begin{equation*}
E_{T}(\text { мо })=E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} . A O\right) \tag{80}
\end{equation*}
$$

During bond formation, the electrons undergo a reentrant oscillatory orbit with vibration of the nuclei, and the corresponding energy $\bar{E}_{\text {osc }}$ is the sum of the Doppler, $\bar{E}_{D}$, and average vibrational kinetic energies, $\bar{E}_{\text {Kvib }}$ :

$$
\begin{equation*}
\bar{E}_{o s c}=n_{1}\left(\bar{E}_{D}+\bar{E}_{K v i b}\right)=n_{1}\left(E_{h v} \sqrt{\frac{2 \bar{E}_{K}}{m_{e} c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{81}
\end{equation*}
$$

where $n_{1}$ is the number of equivalent bonds of the MO, $k$ is the spring constant of the equivalent harmonic oscillator, and $\mu$ is the reduced mass. The angular frequency of the reentrant oscillation in the transition state corresponding to $\bar{E}_{D}$ is determined by the force between the central field and the electrons in the transition state. The force and its derivative are given by

$$
\begin{equation*}
f(R)=-\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}} \tag{82}
\end{equation*}
$$

and

$$
\begin{equation*}
f^{\prime}(a)=2 \frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}} \tag{83}
\end{equation*}
$$

such that the angular frequency of the oscillation in the transition state is given by

$$
\begin{equation*}
\omega=\sqrt{\frac{\left[\frac{-3}{a} f(a)-f^{\prime}(a)\right]}{m_{e}}}=\sqrt{\frac{k}{m_{e}}}=\sqrt{\frac{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}} \tag{84}
\end{equation*}
$$

where $R$ is the semimajor axis $a$ or the semiminor axis $b$ depending on the eccentricity of the bond that is most representative of the oscillation in the transition state. $C_{1 o}$ is the fraction of the $\mathrm{H}_{2}$-type ellipsoidal MO basis function of the oscillatory transition state of a chemical bond of the group, and $C_{2 o}$ is the factor that results in an equipotential energy match of the participating at least two atomic orbitals of the transition state of the chemical bond. Typically, $C_{1 o}=C_{1}$ and $C_{2 o}=C_{2}$. The kinetic energy, $E_{K}$, corresponding to $\bar{E}_{D}$ is given by Planck's equation for functional groups:

$$
\begin{equation*}
\bar{E}_{K}=\hbar \omega=\hbar \sqrt{\frac{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}} \tag{85}
\end{equation*}
$$

The Doppler energy of the electrons of the reentrant orbit is

$$
\begin{equation*}
\bar{E}_{D} \cong E_{h \nu} \sqrt{\frac{2 \bar{E}_{K}}{m_{e} c^{2}}}=E_{h \nu} \sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{1 o} C_{2 o} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}}} \tag{86}
\end{equation*}
$$

$\bar{E}_{\text {osc }}$ given by the sum of $\bar{E}_{D}$ and $\bar{E}_{K v i b}$ is

$$
\begin{equation*}
\bar{E}_{\text {osc }}(\text { group })=n_{1}\left(\bar{E}_{D}+\bar{E}_{\text {Kvib }}\right)=n_{1}\left(E_{h v} \sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}}{m_{e}}}}{m_{e} c^{2}}}+E_{v i b}\right) \tag{87}
\end{equation*}
$$

$E_{h v}$ of a group having $n_{1}$ bonds is given by $E_{T}(м о) / n_{1}$ such that

$$
\begin{equation*}
\bar{E}_{\text {osc }}=n_{1}\left(\bar{E}_{D}+\bar{E}_{\text {Kvib }}\right)=n_{1}\left(E_{T}(м о) / n_{1} \sqrt{\frac{2 \bar{E}_{K}}{M c^{2}}}+\frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}\right) \tag{88}
\end{equation*}
$$

$E_{T+\text { osc }}($ Group $)$ is given by the sum of $E_{T}\left(\right.$ мо ) (Eq. (79)) and $\bar{E}_{\text {osc }}$ (Eq. (88)):
$E_{T+\text { osc }}($ Group $)=E_{T}($ мо $)+\bar{E}_{\text {osc }}$

$$
\begin{aligned}
& =\binom{\left(\begin{array}{l}
-\frac{n_{1} e^{2}}{8 \pi \varepsilon_{0} \sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}\left[c_{1} c_{2}\left(2-\frac{a_{0}}{a}\right) \ln \frac{a+\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}{a-\sqrt{\frac{a a_{0}}{2 C_{1} C_{2}}}}-1\right.
\end{array}\right]}{+E_{T}(A O / H O)+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} \cdot A O\right)}\left(\begin{array}{l}
{\left[\sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{o} R^{3}}}}{m_{e}}}\right.} \\
1+\sqrt{\frac{m_{e} c^{2}}{2}}
\end{array}\right]+n_{1} \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}} . \\
& =\left(E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} \cdot A O\right)\right)\left[\sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{o} R^{3}}} \frac{m_{e}}{m_{e} c^{2}}}{1}}\right]+n_{1} \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}}
\end{aligned}
$$

The total energy of the functional group $E_{T}($ group $)$ is the sum of the total energy of the components comprising the energy contribution of the MO formed between the participating atoms, E(basis energies), the change in the energy of the AOs or HOs upon forming the bond $\left(E_{T}\left(\right.\right.$ atom-atom, $\left.\left.m s p^{3} . A O\right)\right)$, the energy of oscillation in the transition state, and the change in
magnetic energy with bond formation, $E_{\text {mag }}$. From Eq. (89), the total energy of the group $E_{T}$ (Group) is
$E_{T}($ Group $)=\binom{($ E(basis energies $)+E_{T}\left(\right.$ atom - atom, $\left.\left.m s p^{3} . A O\right)\right)\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{0} R^{3}}} \frac{m_{e}}{m_{e} c^{2}}}{}}\right]}{+n_{1} \bar{E}_{\text {Kvib }}+E_{m a g}}$
The change in magnetic energy $E_{\text {mag }}$ which arises due to the formation of unpaired electrons in the corresponding fragments relative to the bonded group is given by

$$
\begin{equation*}
E_{\text {mag }}=c_{3} \frac{2 \pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2} r^{3}}=c_{3} \frac{8 \pi \mu_{o} \mu_{B}^{2}}{r^{3}} \tag{91}
\end{equation*}
$$

where $r^{3}$ is the radius of the atom that reacts to form the bond and $c_{3}$ is the number of electron pairs.

$$
\begin{equation*}
E_{T}(\text { Group })=\binom{\left(E(\text { basis energies })+E_{T}\left(\text { atom }- \text { atom, } m s p^{3} \cdot A O\right)\right)\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{C_{10} C_{20} e^{2}}{4 \pi \varepsilon_{o} R^{3}}} \frac{m_{e}}{m_{e} c^{2}}}{}}\right]}{+n_{1} \bar{E}_{\text {Kvib }}+c_{3} \frac{8 \pi \mu_{o} \mu_{B}^{2}}{r^{3}}} \tag{92}
\end{equation*}
$$

The total bond energy of the group $E_{D}($ Group $)$ is the negative difference of the total energy of the group (Eq. (92)) and the total energy of the starting species given by the sum of $c_{4} E_{\text {initial }}\left(c_{4} A O / H O\right)$ and $c_{5} E_{\text {initial }}\left(c_{5} A O / H O\right)$ :

$$
E_{D}(\text { Group })=-\left(\begin{array}{l}
\left.(\text { E(basis energies })+E_{T}\left(\text { atom }- \text { atom }, m s p^{3} \cdot A O\right)\right)\left[1+\sqrt{\frac{2 \hbar \sqrt{\frac{\frac{C_{10} C_{2 o} e^{2}}{4 \pi \varepsilon_{o} R^{3}}}{m_{e}}}}{m_{e} c^{2}}}\right. \tag{93}
\end{array}\right)
$$

In the case of organic molecules, the atoms of the functional groups are energy matched to the $C 2 s p^{3} \mathrm{HO}$ such that

$$
\begin{equation*}
E(A O / H O)=-14.63489 \mathrm{eV} \tag{94}
\end{equation*}
$$

For example, of $E_{\text {mag }}$ of the $C 2 s p^{3} \mathrm{HO}$ is:

$$
\begin{equation*}
E_{\text {mag }}\left(C 2 s p^{3}\right)=c_{3} \frac{8 \pi \mu_{o} \mu_{B}^{2}}{r^{3}}=c_{3} \frac{8 \pi \mu_{o} \mu_{B}^{2}}{\left(0.91771 a_{0}\right)^{3}}=c_{3} 0.14803 \mathrm{eV} \tag{95}
\end{equation*}
$$

Each molecule, independently of its complexity and size, is comprised of functional groups wherein each present occurs an integer number of times in the molecule. The total bond energy of the molecule is then given by the integer-weighted sum of the energies of the functions groups corresponding to the composition of the molecule. Thus, integer formulas can be constructed easily for molecules for a given class such as straight-chain hydrocarbons considered as an example infra. The results demonstrate how simply and instantaneously molecules are solved using the classical exact solutions. In contrast, quantum mechanics requires that wavefunction are nonlinear, and any sum must be squared. The results of Millsian disprove quantum mechanics in this regard, and the linearity and superposition properties of Millsian represent a breakthrough with orders of magnitude reduction in complexity in solving molecues as well as being accurate physical representations rather than pure mathematical curve-fits devoid of a connection to reality.

## C. Total Energy of Continuous-Chain Alkanes

$E_{D}\left(C_{n} H_{2 n+2}\right)$, the total bond dissociation energy of $C_{n} H_{2 n+2}$, is given as the sum of the energy components due to the two methyl groups, $n-2$ methylene groups, and $n-1 \quad C-C$ bonds where each energy component is given by Eqs. (14.590), (14.625), and (14.641), respectively. Thus, the total bond dissociation energy of $C_{n} H_{2 n+2}$ is

$$
\begin{align*}
E_{D}\left(C_{n} H_{2 n+2}\right) & =E_{D}(C-C)_{n-1}+2 E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{3}\right)+(n-2) E_{D_{\text {alkane }}}\left({ }^{12} \mathrm{CH}_{2}\right)  \tag{96}\\
& =(n-1)(4.32754 \mathrm{eV})+2(12.49186 \mathrm{eV})+(n-2)(7.83016 \mathrm{eV})
\end{align*}
$$

The experimental total bond dissociation energy of $C_{n} H_{2 n+2}, E_{D_{\text {exp }}}\left(C_{n} H_{2 n+2}\right)$, is given by the negative difference between the enthalpy of its formation $\left(\Delta H_{f}\left(C_{n} H_{2 n+2}(\right.\right.$ gas $\left.)\right)$ ) and the sum of the enthalpy of the formation of the reactant gaseous carbons $\left(\Delta H_{f}(C(g a s))\right)$ and hydrogen $\left(\Delta H_{f}(H(g a s))\right)$ atoms:

$$
\begin{align*}
E_{D_{\text {exp }}}\left(C_{n} H_{2 n+2}\right) & =-\left\{\Delta H_{f}\left(C_{n} H_{2 n+2}(\text { gas })\right)-\left[n \Delta H_{f}(C(\text { gas }))+(2 n+2) \Delta H_{f}(H(\text { gas }))\right]\right\}  \tag{97}\\
& =-\left\{\Delta H_{f}\left(C_{n} H_{2 n+2}(\text { gas })\right)-[n 7.42774 \mathrm{eV}+(2 n+2) 2.259353 \mathrm{eV}]\right\}
\end{align*}
$$

where the heats of formation atomic carbon and hydrogen gas are given by [31-32]

$$
\begin{align*}
& \Delta H_{f}(C(\text { gas }))=716.68 \mathrm{~kJ} / \text { mole }(7.42774 \mathrm{eV} / \text { molecule })  \tag{98}\\
& \Delta H_{f}(H(\text { gas }))=217.998 \mathrm{~kJ} / \text { mole }(2.259353 \mathrm{eV} / \text { molecule }) \tag{99}
\end{align*}
$$

## D. 3-21G and 6-31G* Basis Sets Calculations

The energies of the $3-21 \mathrm{G}$ and $6-31 \mathrm{G}^{*}$ basis sets were acquired from Spartan's precomputed database, and the total bond energies $E_{T}$ were determined using Eqs. (100) and (101). Only those molecules were studied using Spartan for which either the total ionization potentials ( $I P_{\text {exp }}$ ) could be calculated from experimental data [33] or for which quantum mechanical total ionization potentials $\left(I P_{Q M}\right)$ could be calculated from values obtained from Gaussian. Due to this limitation, many molecules for which experimental data was available were omitted in the comparison between Spartan and these experimental values; although, Millsian solved them including the major classes of organometallics and coordinate compounds to typically within less than $0.1 \%$.

$$
\begin{align*}
& E_{T}=E-\text { Tot } I P_{\text {exp }}  \tag{100}\\
& E_{T}=E-\text { Tot } I P_{Q M} \tag{101}
\end{align*}
$$

## III. RESULTS AND DISCUSSION

Well over 300 functional groups have been solved classically and comprise the database for Millsian such that the program can provide essentially instant, exact solutions and renderings for practically an infinite number of molecules (for 300 functional groups the approximate number is 300 raised to the $n-1^{\text {th }}$ power of molecules each comprising $n$ atoms where $n=2,3,4, \ldots \infty)$. Representative functional groups are given in Tables 1 and 2. For example, using Eq. (96), $E_{D}\left(C_{n} H_{2 n+2}\right)$ was determined for propane, butane, pentane, hexane, heptane, octane, nonane, decane, undecane, dodecane, and octadecane [1] to compare to the available experimental values. The latter were determined from the corresponding experimental $\Delta H_{f}\left(C_{n} H_{2 n+2}(\right.$ gas $\left.)\right)$ [32] and Eqs. (97-99). The results of the determination of the total bond energies are given in Table 6. Similarly, a large array of functional groups and molecules per class for which experimental data was available is given in Tables 6-74. Here, the total bond energies of exemplary organic, silicon, boron, organometallic, and coordinate molecules whose designation is based on the main functional group were calculated using the functional group composition and the corresponding energies derived previously [1] and compared to the experimental values. References for the experimental values are mainly from Ref. [33-36], and they are given for each compound in Ref. [1]. For each molecule, the calculated results is based on first principles and given in closed-form, exact equations containing fundamental constants and integers only. The agreement between the experimental and calculated results is excellent. And, unlike previous curve-fitting approaches, the exact geometric parameters, current densities, and energies are given for every electron. Exact representations based on these solutions are given for some exemplary molecules in Figures 5-14. In the case of a translucent view of the
charge-density, the orbitals of the atoms at their radii, the ellipsoidal surface of each H or $\mathrm{H}_{2}$ type ellipsoidal MO that transitions to the corresponding outer shell of the atom(s) participating in each bond, and the hydrogen nuclei (red, not to scale) are shown. In the case of a opaque view of the charge-density, the outer orbitals of the atoms at their radii and the ellipsoidal surface of each H or $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the corresponding outer shell of the atoms participating in each bond are shown.

The Spartan results were broken down into four sets of tests. The Spartan energy $E$ was obtained for both the $3-21 \mathrm{G}$ and $6-31 \mathrm{G}^{*}$ basis sets, and the total bond energy $E_{T}$ was calculated for each basis set using the quantum mechanical ionization potentials (Eq. 101), as is standard practice, and also using experimental ionization potentials (Eq 100) which was a more direct test against experimental data. A relative paucity of Spartan results could actually be tested against experimental data compared to Millsian due to the lack of experimental ionization energy data for higher $Z$ atoms. Table 75 gives the results of Millsian 1.0, the results with 3-21G and 6$31 \mathrm{G}^{*}$ basis sets generated from a pre-computed Spartan database, and the experimental values. The Millsian results were consistently within a relative deviation of less than $1 \%$, being typically $<0.1 \%$, and the accuracies were very stable across all of the classes of molecules. Where errors of greater than $0.1 \%$ occurred, the atypical result was almost always due to the comparison of vacuum theoretical energies to crystalline experimental data since the gas-phase data was not available. In contrast, the Spartan results with $3-21 G$ and $6-31 G^{*}$ deviated by a wide range of relative errors depending on functional group type and basis set and produced large errors even for it best performance. Spartan 3-21G and 6-31G* typically gave $>30 \%$ relative error compared to experimental values even for simple straight-chain alkanes. Errors for some of the molecule classes were typically greater than $100 \%$ and even surpassed $1000 \%$ as the functional group complexity increased beyond straight-chain alkanes. Furthermore, the comparison between the two basis sets showed discrepancies with the errors at times of opposite sign indicating even a lack of internal consistency between the basis sets. In fact, as the molecules deviated from the very simple straight-chain alkanes to more complex molecules such as halobenzenes, the results appeared random without any discernible pattern to the failures. The corresponding impact to the fidelity of the data in terms of applications is enormous. Millsian typically gives 3 to 4 significant-figure accuracy compared to 1 to 2 significant figures for Spartan rendering it practically useless.

In the sets where the Spartan results were calculated using quantum mechanical ionization potentials, $I P_{Q M}$, as is standard practice, the relative deviation ( $>20 \%$ ) was less than that for the corresponding use of the experimental values, and the trend was highly consistent across classes of molecules. Yet, theoretical calculations that attempt to omit unaccounted for
properties that they might 'cancel out,' producing a better number by the subtraction of two numbers with large errors is of questionable validity. This is evident in the cases of the method using $I P_{Q M}$ 's where it was occasionally susceptible to very large discrepancies surpassing $100 \%$ and even $1000 \%$.

It is clear from these results that basis-set algorithms such as those using the 3-21G and $6-31 \mathrm{G}^{*}$ basis sets can only match experimental results within a limited set of molecules for which they are optimized. Since the results have substantial errors even for the best results, the usefulness to industry application is suspect. This issue is compounded by the fact that the procedures are not based on physical laws; whereas, Millsian is. If electrons do obey physical laws as the results of Millsian confirm, then the basis-set approach is no more useful than curve fitting, and there can be no inherent physical insight or predictiveness to be gained from these computational methods. Without even testing the geometry, it is easy to conclude that quantum mechanical solutions to molecules are not realistic from their inability to correctly render the charge density as well as the predict energy. When comparing the rendering of the simple alkane butane ( $C_{4} H_{10}$ ) using the two basis sets (Figures 15A-B) neither shows any resemblance to butane in that they are not even symmetrical, the edge is created artificially and arbitrarily, and the $3-31 \mathrm{G}$ basis set rendering has a very different density pattern than that obtained using the 321 G basis set. This inconsistent and unnatural QM result is contrast with the exact classical solution of butane given in Figure 5 that matches butane for all of its measurable parameters.

## IV. CONCLUSION

The current scientific software market is highly fragmented and based on academic-based curve-fitting models; whereas, Millsian 1.0 is the only modeling technology based on fundamental physical laws. In this study we compared the energies of exact classical solutions of molecules generated by Millsian 1.0 to energies from Spartan's pre-computed database using $3-21 \mathrm{G}$ and $6-31 \mathrm{G}^{*}$ basis sets, and experimental values. The Millsian results were consistently within an average relative deviation of about $0.1 \%$ of the experimentally values; whereas, the Spartan 3-21G and 6-31G* results deviated over a wide range of relative error, typically being a factor of three orders of magnitude greater with a large percentage of catastrophic failures, depending on functional group type and basis set. The results indicate that the basis-set computational approach is prone to erroneous numerical results. The failures undermine the premise of using a purely computational model devoid of any physical basis since it cannot render true representations based the underlying physics; consequently, such models lack general predictive utility.

In contrast, Millsian modeling technology based on physical laws predicts exact solutions for molecules for the first time in history. The Millsian competitive advantage includes rendering true molecular structures providing precise bonding characteristics, spatial and temporal charge distributions, and energies of every electron in every bond and bonding atom. These exact solutions can provide precise chemical and engineering properties of molecules and thus materials. Thus, this new technology may create new opportunities for discovery of new chemical processes, new molecules, new synthetic pathways, new materials, and new uses for existing molecules. Exact solutions may facilitate drug design, with the identification of biologically active sites and structures and predict optimal synthetic pathways, products, and yields. This represents a major breakthrough in the chemical and material sciences that may impact nearly all businesses involved in material, chemicals, and drug development. New possibilities are enabled at a time that industries are expanding or changing their focus with a commensurate increased challenge to current modeling capabilities. Pharma, for example, can benefit from the real-time interactive exact rendering of large bio-molecules such as proteins (Figure 13) and DNA (Figure 14) that are enabled by Millsian at a time when the industry is shifting emphasis from small molecules to biotechnology.

## Figure Captions

Figure 1. A bound electron is a constant two-dimensional spherical surface of charge (zero thickness, total charge $=\theta=\pi$, and total mass $=m_{e}$ ), called an electron orbitsphere. The corresponding uniform current-density function having angular momentum components of $\mathbf{L}_{x y}=\frac{\hbar}{4}$ and $\mathbf{L}_{z}=\frac{\hbar}{2}$ give rise to the phenomenon of electron spin.

Figures 2A-B. The bound electron exists as a spherical two-dimensional supercurrent (electron orbitsphere), an extended distribution of charge and current completely surrounding the nucleus. Unlike a spinning sphere, there is a complex pattern of motion on its surface (indicated by vectors) that generates two orthogonal components of angular momentum (Figure 1) that give rise to the phenomenon of electron spin. (A) A great-circle representation of the z -axis view of the total current pattern of the $Y_{0}^{0}(\phi, \theta)$ orbitsphere comprising 144 great circle current elements.
(B) A representation of the $\left(-\frac{1}{\sqrt{2}} \mathbf{i}_{x}, \frac{1}{\sqrt{2}} \mathbf{i}_{y}, \mathbf{i}_{z}\right)$-axis view of the total uniform current-density pattern of the $Y_{0}^{0}(\phi, \theta)$ orbitsphere with 144 vectors overlaid on the continuous bound-electron current density giving the direction of the current of each great circle element (nucleus not to scale).

Figure 3. The orbital function modulates the constant (spin) function, (shown for $\mathrm{t}=0$; three-dimensional view).

Figures 4A-B. Prolate spheroidal $H_{2} \mathrm{MO}$, an equipotential minimum energy twodimensional surface of charge and current that is stable to radiation. (A) External surface showing the charge density that is proportional to the distance from the origin to the tangent to the surface with the maximum density of the MO closest to the nuclei, an energy minimum. (B) Prolate spheroid parameters of molecules and molecular ions where $a$ is the semimajor axis, $2 a$ is the total length of the molecule or molecular ion along the principal axis, $b=c$ is the semiminor axis, $2 b=2 c$ is the total width of the molecule or molecular ion along the minor axis, $c^{\prime}$ is the distance from the origin to a focus (nucleus), $2 c^{\prime}$ is the internuclear distance, and the protons are at the foci.

Figure 5. $C_{4} H_{10} \mathrm{MO}$ comprising a linear combination of $\mathrm{C}-\mathrm{H}$-bond MOs and $\mathrm{C}-\mathrm{C}-$ bond MOs of the two methyl and two methylene groups. (A) Color scale, translucent view of the charge-density of the $C-C$-bond and $C-H$-bond MOs and the $C_{\text {butane }} 2 s p^{3}$ HOs. Each $C-C-$ bond MO comprises a $H_{2}$-type ellipsoidal MO bridging two $C_{\text {butane }} 2 s p^{3}$ HOs. For each $\mathrm{C}-\mathrm{H}$ and the $\mathrm{C}-\mathrm{C}$ bond, the ellipsoidal surface of the $\mathrm{H}_{2}$-type ellipsoidal MO that transitions to the $C_{\text {butane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {butane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown. (B)-(C) Opaque view and translucent view high-lighting the $C-C$-bond MOs of the charge-density of the $\mathrm{C}_{4} H_{10} \mathrm{MO}$.

Figure 6. $\mathrm{C}_{18} \mathrm{H}_{38}$ MO comprising a linear combination of $\mathrm{C}-\mathrm{H}$-bond MOs and $\mathrm{C}-\mathrm{C}$ bond MOs of the two methyl and sixteen methylene groups. (A) Opaque view of the chargedensity of the $\mathrm{C}-\mathrm{C}$-bond and $\mathrm{C}-\mathrm{H}$-bond MOs. Each $\mathrm{C}-\mathrm{C}$-bond MO comprises a $\mathrm{H}_{2}$-type ellipsoidal MO bridging two $C_{\text {octadecane }} 2 s p^{3}$ HOs. (B) Translucent view high-lighting the $C-C$ -
bond MOs of the charge-density of the $C_{18} H_{38}$ MO. For each $C-H$ and the $C-C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C_{\text {octadecane }} 2 s p^{3} \mathrm{HO}$, the $C_{\text {octadecane }} 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

Figure 7. Opaque pentagonal view of the charge-density of the $C_{60} \mathrm{MO}$ high-lighting the twenty hexagonal and twelve pentagonal units joined together such that no two pentagons share an edge. The six-six ring edges are $C=C$ bonds and the five-five ring edges are $C-C$-bonds such that each hexagon is comprised of alternating $C=C$-bond MOs and $C-C$-bond MOs and each pentagon is comprised of only $C-C$-bond MOs.

Figure 8. $C_{60} \mathrm{MO}$ comprising a hollow cage of sixty carbon atoms bound with the linear combination of sixty sets of $C-C$-bond MOs bridged by 30 sets of $C=C$-bond MOs. A $C=C$ group is bound to two $C-C$ groups at each vertex carbon atom of $C_{60}$. Color scale, translucent pentagonal view of the charge-density of the $C_{60}$-bond MO with each $C 2 s p^{3} \mathrm{HO}$ shown transparently. For each $C-C$ and $C=C$ bond, the ellipsoidal surface of the $H_{2}$-type ellipsoidal MO that transitions to the $C 2 s p^{3} \mathrm{HO}$, the $C 2 s p^{3} \mathrm{HO}$ shell, inner most $C 1 s$ shell, and the nuclei (red, not to scale), are shown.

Figure 9. Color scale, translucent view of the charge-density of benzoic acid.
Figure 10. Color scale, translucent view of the charge-density of adenine.
Figure 11. Color scale, translucent view of the charge-density of phenylborinic anhydride.

Figure 12. Color scale, opaque view of the charge-density of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3} \operatorname{SnSn}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}$.
Figure 13. Color scale, opaque view of the charge-density of representative polypeptide phenylalanine-leucine-glutami ne-aspartic acid (phe-leu-gln-asp). Using the amino-acid functional groups, proteins of any length and complexity may be rendered.

Figure 14. Color scale rendering of the charge-density of the representative DNA ACTGACTGACTG fragment TGACTGACTGAC • Using the nucleotide functional groups, DNA or RNA of any length and complexity may be rendered.

Figures 15A-B. Comparison of the rendering of the simple alkane butane ( $C_{4} H_{10}$ ) using the two basis sets with an arbitrary cutoff of the all-space density at $95 \%$. (A) $C_{4} H_{10}$ rendered using the Spartan with the $3-21 \mathrm{G}$ basis set. (B) $C_{4} H_{10}$ rendered using the Spartan with the 331G* basis set. Neither shows any resemblance to butane in that they are not even symmetrical, nor do the density patterns from the two basis sets show any resemblance to each other. The results are not even internally consistent in addition to giving large errors in predicted energies.
